MAYO CLINIC LABORATORIES

Test Definition: TULI

Francisella tularensis Antibody, IgM and IgG, Technical Interpretation, Serum

Overview

Useful For
Interpretation to aid in the diagnosis of tularemia caused by *Francisella tularensis*

Method Name
Only orderable as part of a profile. For more information see TULAB / *Francisella tularensis* Antibody, IgM and IgG, ELISA, Serum.

Technical Interpretation

NY State Available
Yes

Specimen

Specimen Type
Serum

Specimen Required
Only orderable as part of a profile. For more information see TULAB / *Francisella tularensis* Antibody, IgM and IgG, ELISA, Serum.

Reject Due To

Specimen Stability Information

Specimen Type	Temperature	Time	Special Container
Serum	Refrigerated (preferred)	7 days	
	Frozen	30 days	

Clinical & Interpretive

Clinical Information
Francisella tularensis is a small, intracellular, coccobacillary gram-negative bacterium and is an obligate pathogen in animals and humans, primarily maintained in rabbits, hares, cats, ticks, and deerflies. *F tularensis* is found throughout North America and parts of Asia and, similar to *Brucella* species, is considered a potential agent of bioterrorism. Human infection with *F tularensis* usually occurs through inhalation of infected aerosols, ingestion of contaminated meat or

water, handling of diseased or sick animals, or through the bite of an infected arthropod (eg, tick, deerflies).

Following a 3- to 5-day incubation period, the clinical manifestations of infection with *F tularensis* differ primarily depending on the site and route of infection. The most common form of disease is ulceroglandular (45%-80% of cases), which is associated with an arthropod (or animal) bite or another cause of skin barrier compromise. This leads to development of a painful papule that ultimately ulcerates allowing the bacterium to enter the lymphatic system. Glandular tularemia is similar in presentation to ulceroglandular disease; however, it lacks the ulceration and, more frequently, causes septicemia. Other, less frequent clinical manifestations include oculoglandular (Parinaud syndrome), oropharyngeal and gastrointestinal disease, and pneumonic or typhoidal tularemia.

Diagnostic testing options for *F tularensis* primarily include culture and serology. Providers suspecting tularemia should collect appropriate specimens (eg, skin lesion biopsy, lymph node aspirates) promptly and send for culture. The microbiology laboratory should be alerted to the possibility of *F tularensis* to ensure that appropriate safety measures are taken to protect the laboratory technologists. Growth on culture is a definitive means of making a diagnosis of tularensis. Serologic testing may be used to support a diagnosis of current or recent tularensis in patients who are IgM positive, who seroconvert to IgM, or who are IgG positive in paired sera collected 2 to 3 weeks apart.

Reference Values

Only orderable as part of a profile. For more information see TULAB / *Francisella tularensis* Antibody, IgM and IgG, ELISA, Serum.

IgM: Negative
IgG: Negative

Reference values apply to all ages.

Interpretation

IgM result	IgG result	Interpretation
Negative	Negative	No antibodies to *Francisella tularensis* detected. Antibody response may be negative in samples collected too soon following infection/exposure. Repeat testing on a new sample in 1 to 2 weeks if clinically indicated.
Positive	Negative	IgM class antibodies to *F tularensis* detected, suggesting current or recent infection. Repeat testing in 1 to 2 weeks to detect seroconversion of IgG may be considered to confirm the diagnosis.
Positive	Borderline	
Borderline	Negative	Questionable presence of IgM antibodies to *F tularensis*. Consider repeat testing in 1 to 2 weeks.
Borderline	Positive	IgG class antibodies to *F tularensis* detected suggesting recent or past infection. Clinical correlation alongside presentation, exposure history and other laboratory findings required.

Borderline	Borderline	Questionable presence of IgM and IgG class antibodies to *F tularensis*. Consider repeat testing in 1 to 2 weeks.
Positive	Positive	IgM and IgG class antibodies to *F tularensis* detected suggesting current, recent or past infection. Cross-reactions may occur in patients with a current or prior Brucella infection. Clinical correlation alongside presentation, exposure history and other laboratory findings required.
Negative	Positive	IgG class antibodies to *F tularensis* detected suggesting recent or past infection. Clinical correlation alongside presentation, exposure history and other laboratory findings required.
Negative	Borderline	Questionable presence of IgG antibodies to *F tularensis*. Consider repeat testing in 1 to 2 weeks.

Cautions

False-negative results may occur in specimens collected too soon following symptom onset, prior to the development of a detectable immune response. Repeat testing on new specimens collected 2 to 4 weeks later may be helpful.

False-positive results may occur in patients previously or currently infected with *Brucella* species. Other less frequent causes of cross-reactivity that have been reported include prior infection with *Yersinia*, *Salmonella*, or *Legionella* species.

IgM-class antibodies may be detectable as soon as 1 week after symptom onset and may remain detectable for multiple years following resolution of disease in some individuals. Therefore, an IgM positive result may not indicate current or recent infection in some cases.

Multiple subspecies of *Francisella tularensis*, including *F tularensis* subspecies *tularensis*, *F tularensis* subspecies *holarctica,* and *F tularensis* subspecies *novicida* are found throughout the northern hemisphere, including in the United States. The IgM and IgG anti-*F tularensis* enzyme-linked immunosorbent assays used at Mayo Clinic Laboratories are based on the lipopolysaccharide (LPS) antigen of *F tularensis*. Although not directly tested, previous studies indicate that there are no antigenic differences between the LPS of *F tularensis* subspecies *tularensis* and the other subspecies. Therefore, these assays should not be used to differentiate between infection with the various *F tularensis* subspecies.
