

PrecivityAD2, Reflex to Apolipoprotein E,
Plasma

#### Overview

#### **Useful For**

Assisting in the evaluation of adult patients, aged 55 years and older, with signs or symptoms of mild cognitive impairment or dementia who are being assessed for Alzheimer disease and other causes of cognitive decline

Determining APOE E4 status to aid in medical management and treatment decisions when the PrecivityAD2 blood test result is positive

This test **is not intended for** patients younger than 55 years, or for use as a screening test in patients without signs or symptoms of cognitive, or for serial testing for assessment of longitudinal changes.

#### **Reflex Tests**

Test Id	Reporting Name	Available Separately	Always Performed
C2NAP	Precivity-ApoE	No	No

## **Testing Algorithm**

When this test result is positive, then apolipoprotein E testing will be performed at an additional charge.

#### **Highlights**

The PrecivityAD2 blood test measures amyloid beta (Abeta) 42/40 ratio and percent tau phosphorylated at threonine-217 (%p-tau217). The results are then combined and used in a proprietary statistical algorithm to calculate the Amyloid Probability Score 2 (APS2). The APS2, Abeta 42/40 ratio and %p-tau217 are reported, however, individual Abeta42, Abeta40, phosphorylated tau217 and non-phosphorylated tau217 concentrations are not reported. For patients who receive a positive PrecivityAD2 test result, additional testing is performed to measure the apolipoprotein E isoforms E2, E3, and E4.

#### **Method Name**

Immunoprecipitation/Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS)

## **NY State Available**

No

## **Specimen**

#### Specimen Type

Plasma

## **Ordering Guidance**

PrecivityAD2, Reflex to Apolipoprotein E,
Plasma

This blood test is intended for use in patients aged 55 and older with signs or symptoms of mild cognitive impairment or dementia who are undergoing evaluation for Alzheimer disease or other forms of cognitive decline, and who have not had prior apolipoprotein E proteotyping or *APOE* genotyping.

## **Shipping Instructions**

- 1. Specimens must be shipped frozen on dry ice.
- 2. Place labeled aliquot tubes inside a larger tube or vial for transport.

### **Specimen Required**

Supplies: Screw cap micro tube, 2 mL, PCR Performance Tested, Low protein-binding (T983)

Collection Container/Tube: 10 mL Purple top (K EDTA)

**Submission Container/Tube:** Two 2-mL screw cap micro tubes **Specimen Volume:** 3 mL in 2 tubes, each containing 1.5 mL

#### **Collection Instructions:**

- 1. Centrifuge within two hours of collection.
- 2. Label two 2-mL screw-cap micro tubes.
- 3. Aliquot 1.5 mL of plasma into each labeled micro tube.
- 4. Freeze plasma (no longer than 2 hours after collection) at or below -20 degrees C.

#### **Forms**

<u>If not ordering electronically, complete, print, and send a Neurology Specialty Testing Client Test Request</u> (T732) with the specimen.

### **Specimen Minimum Volume**

See Specimen Required

## **Clinical & Interpretive**

#### **Clinical Information**

Alzheimer disease (AD) is defined pathologically by the presence of amyloid plaques and neurofibrillary tangles in the brain. Clinical characteristics include gradual onset of Mild cognitive impairment (MCI), behavioral changes such as apathy, withdrawal, or agitation, and disease progression to middle and later stage dementia. (1,2) Currently, no test detects AD with 100% accuracy; definitive diagnosis occurs at brain autopsy.

Recent availability of anti-amyloid therapies increases the importance of detection of AD at an early stage.(3-5) MCI impacts 12% to 18% of people in the United States over age 60 and is often an initial clinical sign of AD.(6) Establishing or excluding an AD diagnosis with a high degree of certainty at first signs of memory decline may optimize medical management.

Brain amyloid pathology is detectable by amyloid positron emission tomography (PET) scan, cerebrospinal fluid testing, or liquid chromatography tandem mass spectrometry blood biomarker testing with high sensitivity and specificity in patients with MCI and early dementia.(7-12) In all testing modalities, healthcare providers interpret test results in the context of the patient's clinical findings and other clinical work-up, as the neuropathological changes associated with AD can be seen in other forms of dementia and in unaffected individuals.(7,8,13)

The PrecivityAD2 test is an analytically and clinically validated blood test that aids healthcare providers in ruling in or ruling out AD in patients presenting with MCI or dementia. This evaluation simultaneously quantifies specific plasma amyloid beta (Abeta) and tau peptide concentrations to calculate the Abeta42/40 ratio and percent tau phosphorylated at threonine-217 (% p-tau217).(12) The inclusion of plasma analyte ratios has been shown to mitigate the effects of confounding factors such as chronic kidney disease.(14,15) The ratios are combined into a proprietary statistical algorithm to calculate the Amyloid Probability Score 2 (APS2), a numerical value ranging from 0 to 100, that determines whether a patient is positive (has high likelihood) or negative (has low likelihood) for the presence of brain amyloid plaques by amyloid PET scan.

For patients with a positive PrecivityAD2 blood test result, apolipoprotein E (ApoE) proteotyping is performed to determine *APOE* E4 status.

ApoE is a component of several classes of lipoprotein particles, including chylomicron remnants, very-low-density lipoprotein (VLDL), intermediate-density lipoprotein (IDL) and high-density lipoprotein (HDL) and is highly expressed in the liver and brain.(16) The protein has seven isoforms (ApoE1-7), the most common of which are ApoE2, ApoE3 and ApoE4. ApoE isoforms are encoded by the *APOE* gene alleles E1-E7. The E3 allele, most frequent in all populations, has a

PrecivityAD2, Reflex to Apolipoprotein E,
Plasma

frequency range of 50% to 90%, whereas E4 and E2 allele frequencies range from 5% to 35% and 1% to 5%, respectively.(17)

ApoE isoforms differentially influence the buildup of amyloid beta plaques and tau neurofibrillary tangles in the brain. Determination of *APOE* proteotype/genotype status may aid in clinical evaluation for AD in symptomatic patients and can inform decision-making for optimal treatment pathways.(18-21) In recent clinical trials for amyloid-reducing therapies, the E4 allele showed an association with the development of amyloid-related imaging abnormalities (ARIA): cerebral edema (ARIA-E), and cerebral microhemorrhages (ARIA-H).(3,4)

#### Reference Values

Amyloid Probability Score 2 (APS2) (range of 0-100):

Negative: 0-47 Positive: 48-100

#### Abeta42/40 Ratio:

> or =0.095 Consistent with absence of amyloid plaques

#### Percent p-tau217:

<4.2% consistent with absence of brain amyloid plagues

#### ApoE Proteotype

E2/E2, E2/E3, E2/E4, E3/E3, E3/E4, E4/E4

- -E3 is the most common allele.
- -E4 allele is associated with increased risk of amyloid plaques.
- -E2 allele is associated with lower risk of amyloid plaques.

### Interpretation

The Amyloid Probability Score 2 (APS2) result is a composite score ranging from 0 to 100 that demonstrates the strongest correlation with brain amyloid pathology compared to the individual biomarkers (amyloid beta [Abeta] 42/40 ratio or percent tau phosphorylated at threonine-217 [%p-tau217]), considered separately. Discordance of the individual biomarkers can occur.

Table 1. Amyloid Probability Score and Interpretation

APS2		Interpretation	
0-47	Negative	Consistent with a negative amyloid positron emission	
		tomography (PET) scan; reflects a low likelihood of	
		brain amyloid plaques and is therefore not consistent	
		with a neuropathological diagnosis of Alzheimer	
		disease (AD).	
48-100	Positive	Consistent with a positive amyloid PET scan; reflects a	
		high likelihood of brain amyloid plaques, one of the	
		neuropathological findings of AD.	

For apolipoprotein E (ApoE) testing, there are six possible allele combinations for AD risk interpretation.

PrecivityAD2, Reflex to Apolipoprotein E,
Plasma

ApoE proteotyping determines which ApoE protein types are present in the submitted sample. The protein types detected determine the presence of E2, E3, and/or E4 alleles, corresponding to the patient's *APOE* genotype (see Table 2).

Table 2. Proteotype Interpretation

Proteotype	Corresponding	Interpretation	
result	genotype		
ApoE2/ApoE2	APOE2/APOE2	E2/E2 homozygous individuals have a	
		significantly decreased risk for AD	
		compared to E3/E3 and E4 carriers.	
ApoE2/ApoE3	APOE2/APOE3	E2/E3 heterozygous individuals have a	
		decreased risk for AD compared to	
		E3/E3, and E4 carriers.	
ApoE2/ApoE4	APOE2/APOE4	E2/E4 heterozygous individuals have an	
		increased risk for AD compared to E3/E3,	
		E2/ E2, and E2/E3 proteotypes/	
		genotypes.	
ApoE3/ApoE3	APOE3/APOE3	E3/E3 homozygous individuals are most	
		common and have decreased risk for AD	
		com- pared to E4 carriers, and increased	
		risk compared to E2/E2 and E2/E3	
		proteotypes/genotypes.	
ApoE3/ApoE4	APOE3/APOE4	E3/E4 heterozygous individuals have an	
		approximately three-fold increased risk	
		for AD compared to E4 noncarriers.	
ApoE4/ApoE4	APOE4/APOE4	E4/E4 homozygous individuals have an	
		approximately eight- to twelve-fold	
		increased risk for AD compared to E4	
		noncarriers.	

### **Cautions**

This test is not a standalone test; positive or negative Amyloid Probability Score 2 (APS2) values alone neither rule in nor rule out a diagnosis of Alzheimer disease (AD).

Test results should be used in conjunction with other diagnostic tools such as neurological examination, neurobehavioral tests, imaging, and routine laboratory tests.

False-positive and false-negative test results may occur.

This test uses interpretive data that were derived from clinical studies in a predominantly White US population of patients with mild cognitive impairment or early dementia. The extent of the differences in results (if any) based on individuals of other racial and ethnic groups has not yet been firmly established.

PrecivityAD2, Reflex to Apolipoprotein E,
Plasma

Currently, there is insufficient evidence to support serial testing for the assessment of longitudinal changes in biomarkers, including monitoring response to therapy.

The results of other analyte tests using other methodologies cannot be interpreted in the context of the PrecivityAD2 test.

#### Apolipoprotein E

This test detects only peptides from E2, E3 and E4 proteins and does not detect peptides from rare apolipoprotein E (ApoE) phenotypes.

Although multiple epidemiological studies of diverse ethnic populations have demonstrated increased frequency of the E4 allele in late-onset AD cohorts, the extent of differences in individual risk estimates across different ethnicities has not been established.(22)

The E4 allele is neither necessary nor sufficient for the development of AD; thus, ApoE isoform/APOE allele status cannot be used alone for the diagnosis of AD.(18)

### **Performance**

#### **Method Description**

Plasma specimens undergo immunoprecipitation followed by liquid chromatography tandem mass spectrometry (LC-MS/MS) for the quantification of amyloid beta (Abeta) 42 and Abeta 40 peptide isoform concentrations and phosphorylated and non-phosphorylated tau at amino acid threonine, position 217 (p-tau271 and np-tau217) peptide concentrations. The percent tau phosphorylated at threonine-217 (%p-tau217) is calculated using the following equation: p-tau271/np-tau217\*100. A statistical algorithm combines the Abeta42/40 and %p-tau217 to generate the Amyloid Probability Score 2 (APS2).(Meyer MR, Kirmess KM, Eastwood S, et al. Clinical validation of the PrecivityAD2 blood test: A mass spectrometry-based test with algorithm combining %p-tau217 and Abeta42/40 ratio to identify presence of brain amyloid. Alzheimers Dement. Published online March 16, 2024. doi:10.1002/alz.13764)

PrecivityAD2, Reflex to Apolipoprotein E,
Plasma

For the identification of apolipoprotein E (ApoE) peptides specific to ApoE2, ApoE3, ApoE4 isoforms, patient specimens undergo immunoprecipitation followed by LC-MS/MS. Specific combinations of 'present' and 'absent' peptides are used to determine ApoE proteotype.
